We examine structure–function relationships in a series of \textit{N}-phenylbenzamide (NPBA) derivatives by using computational modeling to identify molecular structures that exhibit both rectification and good conductance together with experimental studies of bias-dependent single molecule conductance and rectification behavior using the scanning tunneling microscopy break-junction technique. From a large number of computationally screened molecular diode structures, we have identified NPBA as a promising candidate, relative to the other structures that were screened. We demonstrate experimentally that conductance and rectification are both enhanced by functionalization of the NPBA 4-carboxamido-aniline moiety with electron donating methoxy groups, and are strongly correlated with the energy of the conducting frontier orbital relative to the Fermi level of the gold leads used in break-junction experiments.

Introduction

According to a recent review,\textsuperscript{1} unimolecular electronics (UME) have remained in a state of constant “adolescence” since the formal establishment of the field by Aviram and Ratner in 1974.\textsuperscript{2} It is partially attributed to the fact that, despite a considerable number of publications, single molecules have yet to prove practical replacements for silicon-based electronic devices, largely because of the difficulties associated with reliably integrating single molecules into complex circuits.\textsuperscript{3} As such, a variety of new directions have been proposed for the development of unimolecular rectifiers. For example, recent work has focused on developing and incorporating UMEs with the goal of regulating the directionality of charge separation and current flow through integrated molecular assemblies.\textsuperscript{4–7}

Unimolecular devices capable of rectifying current—molecular diodes—could be used as a principal component in regulating charge separation and recombination at the dye-semiconductor interface in dye-sensitized photoelectrochemical cells (DSPCs).\textsuperscript{4,7,8} Such diodes have to meet three essential requirements: (1) being relatively small in size (~1 nm), for easy integration into the dyes and to avoid interfering with the electronic structure of the dye, (2) able to respond to a very small applied bias,\textsuperscript{4} and (3) exhibiting a large conductance at 0 V bias so that it does not affect the rate and efficiency of the initial injection.\textsuperscript{9} Guided by these three requirements, we performed an extensive computational screening of a portfolio of promising structures for molecular rectification, which highlighted several promising candidates based on \textit{N}-phenylbenzamide derivatives.\textsuperscript{7}

Many designs of molecular diodes have been proposed and studied.\textsuperscript{4} Many of these designs are similar to those proposed by Aviram and Ratner, and are based on donor-bridge-acceptor assemblies.\textsuperscript{5,9–14} Other designs include fully conjugated systems with substitutions on the core of the molecule,\textsuperscript{15} dipyrromidinyl-diphenyl derivatives,\textsuperscript{16,17} \pi\textsuperscript{-}stacked donor–acceptor cyclophane assemblies,\textsuperscript{18} asymmetrical anchored molecules,\textsuperscript{19–23} and systems with asymmetrically modified electrodes.\textsuperscript{26–29} Recently, design schemes based on a single asymmetric frontier orbital have been proposed.\textsuperscript{4,5,7,20} Even though many molecular rectifier designs show high rectification (RR > 1000), most of them are too complex to be integrated into molecular assemblies for devices such as DSPCs.
Other observations of high rectifications were achieved with systems using different electrode materials or different terminal groups on either side of the junction. As pointed out by previous studies,19,24,25,30,31 molecular rectifiers with asymmetric contacts or terminal groups can induce extrinsic rectification, which is independent of the properties of the molecules themselves. In order to meet the third requirement, it is important to consider the ‘orbital rule’ described by Yoshisawa and co-workers in the case of fully conjugated molecular systems.32 This would determine the best spatial location of the anchoring groups on the molecule to avoid undesirable dephasing effects between the frontier orbital and ensure a high conductance at 0 V.

Here, we focus on the N-phenylenzamide (NPBA) structure (Scheme 1, molecule R1A) and derivatives which are predicted to have both high conductance and rectification. The NPBA structure has several advantages in the context of molecular rectifiers, including its ease of synthesis and stability, that it can be modified with a variety of anchoring groups, and that it can be functionalized on the amide or phenyl groups to produce an extensive range of derivatives with tunable electron-transfer properties.

We have synthesized four molecular rectifiers based on NPBA (Scheme 1) to explore the fundamental structure–property relationship influencing the transport properties of NPBA derivatives. Our selection of the parent NPBA molecule (R1A) is guided by the results of a recent computational study performed by our group, which revealed that both the conductance and rectification of NPBA derivatives are strongly correlated with the energy of the conducting frontier orbital relative to the Fermi level (E_F) of the gold leads used in break junction experiments.7 We have synthesized two NPBA derivatives with N-methyl (R2A) and N-isopropyl (R3A) alkyl functionalities on the parent NPBA molecule. In addition, we have synthesized a NPBA derivative bearing electron donating methoxy groups on the aniline moiety (R4A).

Based on our computational predictions, these chemical modifications were expected to lead to changes in both the conductance and rectification properties, which we explore experimentally here. Several experimental techniques have been established to measure conductance and rectification by individual molecules, including measurements on molecules bridging electrical contacts prepared by patterned lithography,33,34 between stretched micro-wires,35,36 and in between the gold tip and substrate of a scanning tunneling microscope (STM), or an atomic force (AFM) microscope.37–41 All of these experimental methods have demonstrated that single molecules can indeed function as diodes. In this work, the current–voltage (I–V) characteristics of these molecules were examined by the scanning tunneling microscopy break-junction (STM-BJ) technique,41 which probes the bias-dependent conductance of molecules bound between the gold tip and substrate of a scanning tunneling microscope.39–41 Histograms of I–V curves were determined from thousands of break-junction measurements, and the results were correlated with the trends predicted by computational screening.5

It is important to note that the STM-BJ technique measures the I–V characteristics of a single molecule and is inherently different from techniques that measure the I–V characteristics of contacts made with molecular monolayers where many molecules are probed in a given measurement. To date, the highest rectification ratios (RR) measured by the STM-BJ technique is ~200 for molecules linked to gold electrodes with asymmetric anchoring groups in ionic solutions.42 On the other hand, measurement of I–V characteristics from molecular monolayers results in much higher RRs that can range up to several thousand.1,43 Although higher RRs are measured from molecular monolayers, single molecule techniques reduce the effects of intermolecular interactions and molecular packing on the observed I–V characteristics.40 Only single molecules, not monolayers, can meet the needs of molecular electronics.

Results and discussion

The series of NPBA rectifiers shown in Scheme 1 were synthesized via peptide coupling reactions, which enabled the parent NPBA molecule to be derivatized with alkyl groups on the amide group or electron donating groups on the aniline moiety. We expect that these chemical modifications will lead to changes in both the conductance and rectification properties, based on computational results. Fig. 1 shows the experimental histograms of molecular conductance for R1A, R2A, and R4A. The average conductance values measured experimentally and the calculated values are summarized in Table 1. We find that R4A has the highest conductance (2.7 × 10^−4 G0) while R2A (9.0 × 10^−5 G0) has the lowest conductance and is three-fold lower than that of R1A (1.7 × 10^−4 G0). Based on DFT calculations, the decreased conductance of R2A is attributed to the larger dihedral angle between the carbonyl group and the adjacent phenyl ring due to the steric effect of the N-methyl group which increases the dihedral angle from 24° in R1A to 40° in R2A. These results are consistent with recent studies of other systems (e.g., biphenyls)

alkyl group, thus hindering junction formation. 46–48

linear configuration (amide becomes more energetically favorable relative to the

prior studies have shown that the bent (–OMe groups into the 4-amino-aniline fragment of the molecule,

–alkyl groups, we have also introduced electron-donating

–V characteristics, despite the fact that the bent configuration is energetically favored. 49

Considering the Boltzmann distribution and energy difference between the linear and bent configurations, roughly 4% of R2A

molecules are in their linear configuration in solution at room temperature. In addition, the mechanical force imparted by the gold tip pulling away from the surface may also increase the probability of stable junction formation when the energy difference between the bent and linear configuration is relatively small, as is the case with R2A. On the other hand, the energy difference between the bent and linear configuration is much larger in R3A, and only 0.016% of them will be in the linear configuration. We believe this leads to a low yield of stable junctions and is consistent with the experimental results. This finding highlights the importance of investigating not only the electronic properties of the molecule within a junction but also the structural properties of the molecule in solution.

In addition to examining the effect of functionalizing the amide with N-alkyl groups, we have also introduced electron-donating –OMe groups into the 4-amino-aniline fragment of the molecule, as seen in structure R4A. This has shown promising enhancements in both conductance and rectification. In fact, we find that the conductance of R4A (2.9 × 10⁻⁴ G₀) is nearly two-fold higher than the conductance measured for R1A. Since R4A has a similar twist angle in the amide bridge compared to R1A, the increase in conductance is not due to the relative degree of conjugation, as was the case with the alkyl-functionalized NPBA derivatives. Rather, the increase in conductance is attributed to a shift in the HOMO energy associated with the peak in the transmission function, as shown in Fig. 3A. Electron-donating groups on aromatic rings generally increase the energy of the HOMO. Hence, substitution with –OMe shifts the transport channel of R4A (i.e., the HOMO) closest to the Eᵉ by approximately 0.5 eV toward Eᵉ when compared to R1A and R2A. Therefore, the transmission for R4A at Eᵉ is higher than for R1A, which is fully consistent with the higher value of conductance measured.

showing that conductance depends strongly on the degree of conjugation. 5,44,45 In our case, the larger dihedral angle in R2A effectively breaks the conjugation and reduces the transmission probability relative to R1A.

The N-isopropyl molecule R3A was successfully synthesized, but did not result in well-defined conductance plateaus in the STM-BJ measurements. Although the conductance and I–V characteristics of this molecule could not be determined, the lack of a well-defined conductance plateau has been noted previously and suggests that the binding between the target molecule and the leads is not sufficiently strong to form a stable, reproducible junction. In our case, this finding suggests that the functionalization of the amide group with N-alkyl groups changes the structure of the NPBA molecule more profoundly than simply changing the dihedral angle. In fact, prior studies have shown that the bent (E) configuration of the amide becomes more energetically favorable relative to the linear configuration (Z) when the amide is functionalized with alkyl group, thus hindering junction formation. 46–48

To further investigate this, we performed DFT calculations (details in ESI†) to determine the structure of our series of molecules in the gas phase and in solution using the SMD solvation model (Density-based Solvation Model). Tetrachloroethene (or perchloroethylene, PCE) was substituted for 1,2,4-trichlorobenzene (TCB) during the solution phase calculations since TCB is not included in Gaussian 09. PCE and TCB are similar in regard to their high chloride content and unsaturation, and also have similar dielectric constants (ε = 2.27 for PCE compared to ε = 2.24 for TCB). The free energy changes, between the bent and linear configurations of each molecule, are given in Table 2. The calculations reveal that the bent configuration is energetically favored relative to the linear configuration in the N-alkyl functionalized R2A and R3A molecules, whereas the linear configuration is favored in the unsubstituted R1A and R4A molecules.

In STM-BJ experiments, a linear configuration (Fig. 2) is desired since the amine anchoring groups are then suitably oriented for optimal binding to the Au-leads. In the case of R2A, we were able to form a sufficient number of stable junctions to measure the conductance and I–V characteristics, despite the fact that the bent configuration is energetically favored. 49

Paper
Fig. 3B shows the average $I-V$ curves measured for molecules $R_1A$, $R_2A$, and $R_4A$ determined from over 2000 measurements of individual junctions obtained following methods detailed previously. The magnitude of current rectification is quantified by the rectification ratio ($RR = I^+ / I^-$) of forward ($I^+$) and reverse ($I^-$) currents obtained by applying a given bias potential, in the forward and reverse directions, respectively. The rectification ratios (Table 1) for $R_1A$, $R_2A$, and $R_4A$ are 1.3, 1.3, and 1.5, respectively at 0.8 V. These RR values are above the baseline of 1.2 measured for symmetrical non-rectifying molecules (see Experimental methods section) and are comparable to those obtained in a prior report (1.5 at 0.85 V) for asymmetrically coupled stilbene. Although the values are lower than those recently achieved by this technique, our focus here is on the trend in RR. We find that the measured trends are consistent with the trends observed by computational screening of NPBA analogs (Table 1).

The RR s correlate with the energy of the transmission state corresponding to the HOMO, relative to the $E_F$ of the extended system (including the molecule and the gold leads). This effect, previously referred to as the “$E_F$ proximity” effect, suggests that there is a strong correlation between rectification and the energy of the transmission state relative to $E_F$, provided the conducting orbital (HOMO in this case) has an asymmetrical distribution of the electron density with respect to the junction. In this case, rectification was predicted to increase as the energy of the transmission state under zero-bias approaches that of $E_F$. Since the rectification is caused by the asymmetrical energy shifting of the conducting HOMO under positive and negative biases, the degree of rectification under a certain bias is determined by the shifting of the HOMO in and out of the integration window, which is centered at the Fermi level. Therefore, the initial energy position of the HOMO is crucial to the impact of its shifting on the amount of the state inside the integration window; the closer the HOMO to $E_F$, the larger and the earlier the impact it would have.

To isolate this “$E_F$ proximity” effect, we have minimized the effects of differences in coupling between the molecule and the lead by synthesizing molecules all with the same anchoring group, and by using gold leads on both sides of the molecule. Our experimental results demonstrate that significant changes in both conductance and rectification can be achieved by tuning both the conjugation of the NPBA molecule with alkyl...
functional groups and the energy of the HOMO level relative to $E_F$ by adding electron donating groups to the aniline moiety.

**Conclusions**

Guided by computational screening, we have synthesized a series of N-phenylbenzamide derivatives, and characterized their conductance and rectification properties as a function of molecular structure using the scanning tunneling microscopy break junction technique. We find that rectification is increased when the N-phenylbenzamide backbone is functionalized with the electron-donating methoxy groups on the 4-amino-aniline fragment. Electron-donating groups raise the energy of the HOMO, which is the state that dominates conductance since it is closest to the Fermi level. The resulting proximity amplifies rectification, suggesting a simple yet robust design principle for the rational development of molecular rectifiers. Progress in involves using these design principles to explore derivatization of N-phenylbenzamide with other functional groups in order to further increase molecular rectification.

**Experimental methods**

Details regarding the synthesis and characterization of molecules $R_1A$, $R_2A$, $R_3A$, and $R_4A$ and details of our computational methods can be found in the ESI.

Molecular conductance and $I$–$V$ characteristics were measured by using an STM in the break-junction mode. The break-junction technique involves forming and breaking gold point contacts in a solution of the target molecules. Initially, a freshly cut gold wire (0.25 mm diameter, 99.999%, Alfa Aesar) and a mica disk coated with 100 nm of gold (99.999%, Alfa Aesar) were employed as the STM tip and substrate, respectively. The gold-coated substrate was pre-treated in a UV-ozone etcher to remove residual organic impurities immediately before performing STM experiments. The STM-BJ measurements were performed under ambient, room temperature conditions. Initially, ~1000 conductance traces were collected with the pristine gold tip and substrate in order to verify that the tip and substrate were free of contaminants.

The conductance and $I$–$V$ characteristics of the single-molecule contacts were measured in break junctions formed in the presence of a dilute solution of the target molecule (1–10 mM) dissolved in 1,2,4-trichlorobenzene (99%, Sigma Aldrich). The tip was brought into contact with the surface of the substrate until the conductance was greater than 5 $G_0$ ($G_0 = 77.5 \mu S$). The tip was subsequently withdrawn at a rate of 15 nm s$^{-1}$ for a period of 125 ms and held for a period of 150 ms, while a triangular voltage ramp was applied between $+1$ V and $-1$ V. Finally, the tip was withdrawn at 15 nm s$^{-1}$ for a period of 75 ms to break the junction before repeating the process for a total of ~50000 individual traces. The collected traces were analyzed to select traces that maintained a molecular junction during the entire $I$–$V$ ramp (1–10% of all measured traces). A data selection and sorting process, described in detail elsewhere, was then employed to generate histograms of the $I$–$V$ curves to obtain the average $I$–$V$ curve.$^{19}$

Synthesis of Rectifier Molecules

Reagents, solvents and general glassware handling used for synthesis:

4-[(tert-butoxycarbonyl)amino]benzoic acid, 4-[(tert-butoxycarbonyl)amino]aniline, 4-nitrobenzoyl chloride, N-methyl-4-nitroaniline, N-isopropyl-4-nitroaniline, N,N-diisopropylethylamine (DIPeA), trifluoroacetic acid (TFA), and hydrazine monohydrate (reagent purities: 97% or higher) were obtained from Alfa Aesar. 1-Ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDCI) (97%) was purchased from Bachem. 4-(N,N-dimethylamino)pyridine (DMP), and 4-nitro-2,5-dimethoxyaniline, (reagent purities:97% or higher) were obtained from Acros Organics. 5%-palladium on carbon (Evonik E-101 E R/W 5%) was purchased from Strem Chemicals. All the reagents were used as received. For synthetic purposes dichloromethane (CH$_2$Cl$_2$, OmniSolv grade, EMD-Millipore) and tetrahydrofuran (THF, OmniSolv grade, non stabilized, EMD-Millipore) were dried on a Pure Solv MD-5 solvent purification system (Innovative Technology) on activated aluminum oxide before use and were dispensed under nitrogen. 200 proof ethanol (EtOH, Decon labs), and chloroform (CHCl$_3$, ACS grade, stabilized with amylenes, BDH) were used as received. N,N-Diisopropylethylamine (DIPeA) was freshly distilled over potassium hydroxide (KOH) and stored under argon (Ar). The glassware was oven-dried and cooled under nitrogen prior to use. Anhydrous sodium sulfate (Na$_2$SO$_4$), sodium bicarbonate (NaHCO$_3$), citric acid, and sodium chloride (ACS grade) were obtained from JT-Baker. For purification purposes, dichloromethane (ACS grade, stabilized with amylenes, BDH), chloroform (ACS grade, stabilized with amylenes, BDH) ethyl acetate (EtOAc, ACS grade, BDH), and toluene (ACS grade, Macron Fine Chemicals) were used without further purification. For nuclear magnetic resonance studies (NMR), deuterated dimethylsulfoxide (DMSO-d$_6$ containing 0.05% v/v of tetramethylsilane (TMS)) and deuterated chloroform (CDCl$_3$, containing 0.05% v/v TMS) were obtained from Cambridge Isotope Laboratory. Analytical thin layer chromatography (TLC) was conducted on glass-coated silica gel 60 F254 plates obtained from EMD-Millipore. Column chromatography was conducted on silica gel (SiO$_2$, 43–60 μm) provided by Silicycle. Celite 545 was purchased from EMD-Millipore. NMR spectra were recorded on a Varian DPX spectrometer coupled to an Oxford 400 magnet. $^1$H spectra were recorded at 400 MHz, and $^{13}$C NMR at 101 MHz. Chemical shifts are reported versus tetramethylsilane as internal reference. Mass spectrometry was performed on an Agilent G6550A Q-TOF LC/MS with API by direct injection, the compounds were dissolved in methanol at an approximate concentration of 0.5 mg/mL. All the synthesized N-phenylbenzamide derivatives were stored under Ar at -20°C.

Experimental procedures:

4-[(tert-butoxycarbonyl)amino]-N-[4-(tert-butoxycarbonyl)aminophenyl]benzamide

4-[(tert-butoxycarbonyl)amino]benzoic acid (500 mg, 2.11 mmol) was dissolved in a 1:1 mixture of THF and chloroform (50 mL), N,N-diisopropylethylamine (1 mL, 0.747 g, 5.8 mmol) was added and the solution was cooled to 0 °C under nitrogen. 1-Ethyl-3-(3-dimethylaminopropyl)carbodiimide (460 mg, 2.4 mmol, 1.14 eq) was added and the mixture was stirred at 0 °C for 30 minutes. 4-[(tert-
butoxycarbonyl)amino]-aniline (440 mg, 2.11 mmol, 1eq) was added and the mixture stirred at 0 °C under nitrogen for 30 minutes before being slowly warmed to 45 °C. The progression of the reaction was followed by TLC analysis (SiO$_2$, CH$_2$Cl$_2$: 20%-EtOAc). After stirring 2 hours at 45 °C a large amount of solid precipitated and only trace amounts of starting material were detected by TLC; the mixture was cooled to room temperature, and diluted to 100 mL with dichloromethane. The suspension was successively extracted with 5% aqueous NaHCO$_3$ (2 × 100 mL), 5% citric acid (2 × 100 mL) and water (2 × 100 mL). The organic layer was collected and the solvent was evaporated. The crude solid was suspended in toluene (25 mL) and the solvent evaporated. This treatment was repeated two times to eliminate the remaining water. Due to the poor solubility of the resulting material, it was immediately used in the next reaction without further purification. Yield 587 mg (1.37 mmol, 65%), off-white solid, estimated purity by NMR ~90%.

$^1$H-NMR (400 MHz, DMSO-$d_6$) δ (ppm): 9.92 (s, 1H), 9.62 (s, 1H), 9.23 (s, 1H), 7.84 (d, $J = 8.8$ Hz, 2H), 7.58 (d, $J = 9.0$ Hz, 2H), 7.53 (d, $J = 8.8$ Hz, 2H), 7.36 (d, $J = 8.8$ Hz, 2H), 1.44 (s, 9H).

4-amino-N-(4-aminophenyl)benzamide

The crude 4-[(tert-butoxycarbonyl)amino]-N-[4-(tert-butoxycarbonyl)aminophenyl] benzamide (450 mg, 1.05 mmol) was suspended in dichloromethane (50 mL) and trifluoroacetic acid (10 mL) added. The mixture was then stirred at room temperature. After 2 hours the solid was fully dissolved and TLC analysis (SiO$_2$, CH$_2$Cl$_2$:10%-EtOAc) showed that the reaction was complete. The mixture was diluted to 100 mL with dichloromethane and successively washed with a 5% aqueous NaHCO$_3$ solution (3 × 100 mL) then water (2 × 100 mL). The organic layer was collected, dried over Na$_2$SO$_4$, filtered, and the solvent was evaporated. Column chromatography (SiO$_2$, CH$_2$Cl$_2$: 10%-EtOAc) yielded the desired compound as an off-white solid (175 mg, 0.77 mmol, 73%).

$^1$H-NMR (400 MHz, DMSO-$d_6$) δ (ppm): 9.36 (s, 1H), 7.64 (d, $J = 8.6$ Hz, 2H), 7.30 (d, $J = 8.7$ Hz, 2H), 6.55 (d, $J = 8.6$ Hz, 2H), 6.50 (d, $J = 8.7$ Hz, 2H), 5.61 (brs, 2H), 4.84 (brs, 2H).

$^{13}$C-NMR (101 MHz, DMSO-$d_6$) δ (ppm): 165.01, 152.07, 145.05, 129.41, 129.19, 122.54, 122.11, 114.09, 112.95.

N-methyl-4-nitro-N-(4-nitrophenyl)benzamide

4-Nitrobenzoyl chloride (1.50 g, 8.1 mmol) was dissolved in anhydrous dichloromethane (25 mL). N,N-Diisopropylethylamine (2 mL, 1.49 g, 11.6 mmol, 1.4 eq.) was then added under nitrogen and the mixture was cooled to 0 °C. N-methyl-4-nitroaniline (1.01 g, 6.6 mmol, 0.8 eq.) was added and the mixture was allowed to warm to room temperature. The mixture was then refluxed under nitrogen and the progression
of the reaction was monitored by TLC analysis (SiO₂, CH₂Cl₂). After 2 hours the mixture was cooled to room temperature and diluted to 50 mL with dichloromethane. The solution was washed successively with 5% aqueous NaHCO₃ (2 × 50 mL), 5% aqueous citric acid (2 × 50 mL) and water (1 × 50 mL). The organic layer was collected, dried over Na₂SO₄, filtered and the solvent was evaporated. Column chromatography (SiO₂, elution gradient: CH₂Cl₂ to CH₂Cl₂: 2.5%-EtOAc) yielded the desired compound (second eluted band) as a light yellow solid (1.86 g, 6.2 mmol, 94%).

1H-NMR (400 MHz, CDCl₃) δ (ppm): 8.14 (d, J = 8.0 Hz, 2H); 8.11 (d, J = 8.0 Hz, 2H); 7.50 (d, J = 8.0 Hz, 2H); 7.23 (d, J = 8.0 Hz, 2H); 3.58 (s, 3H).

13C-NMR (101 MHz, CDCl₃) δ (ppm): 168.23, 149.42, 148.50, 145.72, 141.00, 129.58, 126.91, 124.94, 123.53, 38.21.

N-methyl-4-amino-N-(4-aminophenyl)benzamide

N-Methyl-4-nitro-N-(4-nitrophenyl)benzamide (0.5 g, 1.66 mmol) was suspended in absolute ethanol (150 mL). The mixture was then purged with argon (3 vacuum-argon cycles). 5%-palladium on carbon (150 mg) was added and the suspension warmed to 70 °C under argon. Hydrazine monohydrate (1.7 mL, 1.74 g, 35 mmol, 21 eq) was added and the mixture refluxed under argon for 4 hours. TLC analysis (SiO₂, CH₂Cl₂:5%- EtOAc) showed complete conversion. The mixture was cooled to room temperature and the mixture filtered over a short Celite plug. The plug was then washed with ethanol (50 mL) and the solvent evaporated to yield the desired compound as a white solid (380 mg, 1.56 mmol, 95%).

1H-NMR (400 MHz, CDCl₃) δ (ppm): 7.16 (d, J = 8.5 Hz, 2H), 6.82 (d, J = 8.6 Hz, 2H), 6.53 (d, J = 8.6 Hz, 2H), 6.41 (d, J = 8.6 Hz, 2H), 3.74 (brs, 2H), 3.64 (brs, 2H), 3.39 (s, 3H).

13C-NMR (101 MHz, CDCl₃) δ (ppm): 170.47, 147.57, 144.55, 136.83, 130.92, 127.81, 125.69, 115.37, 113.51, 38.86.

N-isopropyl-4-nitro-N-(4-nitrophenyl)benzamide

N-Isopropyl-4-nitroaniline (161 mg, 0.89 mmol) was dissolved in anhydrous dichloromethane (20 mL) under nitrogen. N,N-Diisopropylethylamine (1 mL, 747 mg, 5.8 mmol, 6.5 eq.) and 4-(N,N-dimethylamino)pyridine (75 mg, 0.7 eq.) were then added, followed by 4-nitro-benzoyl chloride (600 mg, 3.23 mmol, 3.6 eq). The mixture was refluxed under nitrogen and the progression of the reaction followed by TLC analysis (SiO₂, CH₂Cl₂). Following the first 2 hours of reflux, 3 × 200 mg of 4-nitro-benzoyl chloride (total quantity added 600 mg, 3.23 mmol, 3.6 eq) and 3 × 0.33 mL N,N-diisopropylethylamine (total quantity added, 1 mL, 747 mg, 5.8 mmol, 6.5 eq.) were added over the course of the 6 hours needed to complete the reaction. The mixture was then cooled to room temperature, diluted to 50 mL with dichloromethane and subsequently successively washed with 5% aqueous NaHCO₃ solution (3 × 50 mL),
5% aqueous citric acid solution (3 × 50 mL) and water (1 × 50 mL). The organic layer was collected, dried over Na₂SO₄, filtered and the solvent evaporated. Column chromatography (SiO₂, CH₂Cl₂:0.5%-EtOAc) yielded the desired compound (second eluted band) as a pale yellow solid (220 mg, 0.67 mmol, 75%).

¹H-NMR (400 MHz, CDCl₃) δ (ppm): 8.12 (d, J = 8.9 Hz, 2H), 8.03 (d, J = 8.7 Hz, 2H), 7.40 (d, J = 8.7 Hz, 2H), 7.19 (d, J = 8.8 Hz, 2H), 5.04 (h, J = 6.8 Hz, 1H), 1.26 (d, J = 6.8 Hz, 6H).

¹³C-NMR (101 MHz, CDCl₃) δ (ppm): 168.06, 148.04, 146.83, 145.11, 142.26, 130.93, 128.95, 124.46, 123.39, 49.28, 21.02.

HRMAS (m/z): calc for C₁₆H₁₅N₃O₅⁺H⁺, 330.10845; found, 330.10774.

N-isopropyl-4-amino-N-(4-aminophenyl)benzamide

N-Isopropyl-4-nitro-N-(4-nitrophenyl)benzamide (200 mg, 0.61 mmol) was suspended in absolute ethanol (75 mL). The mixture was purged with argon (3 vacuum-argon cycles). 5%-palladium on carbon (75 mg) was added and the mixture warmed to 70 °C under argon. Hydrazine monohydrate (0.85 mL, 0.87 g, 17 mmol, 28 eq) was added and the mixture refluxed under argon for 2 hours. TLC analysis (SiO₂, CH₂Cl₂:5%-EtOAc) showed complete conversion. The mixture was cooled to room temperature and filtered over a short Celite plug. The plug was washed with ethanol (30 mL) and the solvent evaporated to yield the desired compound as a white solid (151 mg, 0.56 mmol, 92%).

¹H-NMR (400 MHz, CDCl₃) δ (ppm): 7.10 (d, J = 8.2 Hz, 2H), 6.77 (d, J = 8.2 Hz, 2H), 6.51 (d, J = 8.2 Hz, 2H), 6.38 (d, J = 8.1 Hz, 2H), 5.20 – 4.85 (m, 1H), 3.93 – 3.27 (m, 6H).

¹³C-NMR (101 MHz, CDCl₃) δ (ppm): 170.68, 147.06, 145.23, 131.39, 130.81, 130.36, 127.25, 114.80, 113.53, 47.26, 47.26, 21.03.

4-nitro-N-(4-nitro-2,5-dimethoxyphenyl)benzamide

4-Nitrobenzoyl chloride (702 mg, 3.8 mmol) was dissolved in anhydrous dichloromethane (25 mL) under nitrogen. N,N-Diisopropylethylamine (0.68 mL, 508 mg, 4 mmol) was added, followed by 4-nitro-2,5-dimethoxyaniline (500 mg, 2.5 mmol), and the mixture refluxed under nitrogen. The reaction was followed by TLC analysis (SiO₂, CH₂Cl₂). After 2 hours of reflux, 4-nitrobenzoyl chloride (150 mg, 0.81 mmol) and N,N-diisopropylethylamine (0.15 mL, 113 mg, 0.87 mmol) were added and the mixture was refluxed under nitrogen for a further 2 hours. The reaction mixture was then cooled to room temperature, diluted to 100 mL with dichloromethane, and subsequently successively washed with a 5% aqueous NaHCO₃ solution (3 × 50 mL), a 5% aqueous citric acid solution (3 × 50 mL) and water (1 × 50 mL). The organic layer was collected, dried over Na₂SO₄, filtered and the crude mixture was adsorbed
on silica (30 mL). Column chromatography (SiO₂, dry loading, elution gradient CHCl₃:1%-EtOAc to CHCl₃:2%-EtOAc) yielded the desired compound as a yellow solid (715 mg, 2.05 mmol, 82%).

4-amino-\textit{N}-(4-amino-2,5-dimethoxyphenyl)benzamide

![Reaction Scheme]

4-Nitro-\textit{N}-(4-nitro-2,5-dimethoxyphenyl)benzamide (250 mg, 0.72 mmol) was suspended in absolute ethanol (75 mL). The mixture was purged with argon (3 vacuum-argon cycles). 5%-palladium on carbon (75 mg) was added and the suspension warmed to 70 °C under argon. Hydrazine monohydrate (0.85 mL, 0.87 g, 17 mmol, 24 eq) was added and the mixture refluxed under argon for 2 hours. TLC analysis (SiO₂, CH₂Cl₂:10%-EtOAc) showed complete conversion. The mixture was cooled to room temperature and filtered over a short Celite plug. The plug was washed with ethanol (50 mL) and the solvent was evaporated to yield the desired compound as a slightly off-white solid (167 mg, 0.58 mmol, 81%).

\[^{1}\]H-NMR (400 MHz, DMSO-\textit{d}_{6}) \delta (ppm): 8.66 (s, 1H), 7.62 (d, \textit{J} = 8.5 Hz, 2H), 7.20 (s, 1H), 6.55 (d, \textit{J} = 8.5 Hz, 2H), 6.40 (s, 1H), 5.64 (s, 2H), 4.63 (s, 2H), 3.67 (s, 6H).

Computational Details

Description of the Leads:

Figure S1. The electrodes used for extended systems in I-V curve calculations. They consist of 6 layers of 16 gold atoms cut from an Au fcc lattice, with a triad contact motif attached to the (111) surface. The lattice constant is 4.080 Å.

Computational Methods:

The molecules analyzed in Table 2 were optimized at the DFT/B3LYP level using 6-311+G(d,p) basis set as implemented in Gaussian 09 v.C01. The isolated molecule used for transport calculations were optimized in gas phase with DFT/B3LYP level using 6-31++G(d,p) basis set. The molecular junctions were prepared by inserting the molecules in between the two gold leads as shown in Figure S1, attaching through the amine terminal groups. I-V curves were obtained by using the DFT-NEGF approach as implemented in the TranSIESTA computational package. The generalized gradient approximation (GGA) functional PBE was used for the calculations with single-ζ basis set for gold atoms and double-ζ basis set for non-gold atoms as implemented in TranSIESTA. A Monkhorst-Pack k-point grid of 10×10×80 was used to sample the Brillouin zone for the gold electrode and a grid of 10×10×1 for the molecular region. The energy cutoff for the real space grid was set to 200 Ry.

Single-State Tight-binding (TB) Model:

For computational efficiency and from earlier experience, all screening calculations in our recent study were performed with the nanowire leads and the thiolate anchoring groups. However, amine anchoring groups are found to form a better linkage between molecules and scanning tunneling microscope (STM) tips. Hence, we developed a method that enables us to computationally probe the I-V characteristics of molecules with amine anchoring groups that were identified by our screening process. Therefore, results from the screening process should be only able to predict trends in rectification ratio (RR) as a function of molecular structure but may not accurately predict the absolute value for the RR. For this reason, once the screening process is finished, the most promising candidates are selected for a subsequent refining step, in order to obtain an accurate absolute rectification ratio using a more realistic model.
Previous studies\textsuperscript{9,10} have shown that the low-bias molecular rectification is due to the shifting of the transport state (a frontier molecular orbital, i.e. HOMO or LUMO) closest to the Fermi level under the applied bias. Therefore, we can use the single-state tight-binding model for a more realistic calculation for molecules with anchoring groups other than thiolate groups. In this model, the molecule is approximated as one single state, connected to two leads in a tight-binding fashion. For such a system, the transmission function as a function of energy, $\varepsilon$, under a particular applied bias, $V$, can be described by the Breit-Wigner formula:\textsuperscript{11}

\[
T(\varepsilon, V) = \frac{4\Lambda_L \Lambda_R}{[\varepsilon - \varepsilon_0(V)]^2 + (\Lambda_L + \Lambda_R)^2}
\]

where $\varepsilon_0$ is the energy of the isolated state, and $\Lambda_L$ and $\Lambda_R$ are the coupling to the left and right electrodes, respectively. According to this model, rectification is caused only by asymmetric shifting of $\varepsilon_0$ with respect to the applied bias. Hence, we are assuming that the overall shape of the transmission function will not be affected under low bias.

Our single state $\varepsilon_0$ will be spatially localized at the “center of mass” of the conducting molecular state (or gateway orbital) shown in Figure S2. In the case of the present work we have determined that the HOMO of the molecule is the primary orbital responsible for the electronic conductance, and its “center of mass” will determine the position of the single state. With the present molecular orientation, the HOMO is localized on the 4-carboxy-aniline side of the molecule (see Figure S2). Accordingly, when a positive bias is applied, $\varepsilon_0$ increases as the value of applied bias increases, and decreases as the bias decreases.\textsuperscript{10} It is assumed that the bias experienced by the molecule is linearly decreasing from the molecule-lead contact point to the geometric center of the junction. Hence, the change of $\varepsilon_0$ is proportional to distance in the transport direction between the HOMO “center of mass” and closest contact point:

\textbf{Figure S2.} The LDOS for $R1_\Lambda$, $R2_\Lambda$, and $R4_\Lambda$. The green line indicates the center point in the transport direction of the junction (between the gold leads). The red lines indicate the “center of mass” of the conducting molecular states in the transport direction for each molecule.
\[
\varepsilon_0(V) = \varepsilon_0(0) + V \times \frac{\text{state - lead distance}}{\text{junction length}}
\]  

(2)

where \( V \) is the applied bias. Therefore, the transmission function under different bias can be approximated by substituting Eq. (2) into Eq. (1):

\[
T(E, V) = \frac{4\Lambda_L \Lambda_R}{\left\{ E - \left[ \varepsilon_0(0) + V \times \frac{\text{state - lead distance}}{\text{junction length}} \right] \right\}^2 + (\Lambda_L + \Lambda_R)^2}
\]

(3)

Assuming that the shape of transmission function does not change under low bias, \( \varepsilon_0(0), \Lambda_L, \) and \( \Lambda_R \) can be obtained by fitting the dominant transmission peak using Eq. (3), treating these three quantities as parameters, and setting \( V \) to 0. Meanwhile, the spatial position of \( \varepsilon_0(0) \) can be approximated by using the coordinates of the center of mass of the HOMO. The state-lead distance is the distance between the molecule-lead contact point and the center of mass of the HOMO, projected onto the transport direction. Once all the parameters are obtained, the transmission function of the dominant transport state under different biases can be calculated, and in turn the current under those biases is computed.

**Table S1.** Parameters from zero-bias transmission function fitted by Eq. (4). Units are eV.
